NUMERICAL METHODS
ECSE 543 - ASSIGNMENT 1

MIDO ASSRAN - 260505216

QUESTION 1

Part a. The Choleski implementation is provided in **Listing 2**.

Code structure. To maintain portability and modularity of the code, object oriented principles were used for the software architecture. The choleski implementation is included in the *CholeskiDecomposition()* class. The *solve(A, b)* method solves the linear system of equations shown in equation (1) by performing choleski elimination.

$$(1) \qquad\qquad\qquad\qquad Ax = b$$

The method accepts the matrix A, and the vector b (both of which will eventually be overwritten by the algorithm in order to conserve memory resources), and returns the vector x corresponding to the solution of equation (1). The algorithm works in two stages. The first stage performs a choleski factorization of A into LL^T (overwriting the lower triangular part of A by L), while simultaneously solving lower triangular system $Ly = b$ using forward substitution (overwriting b with the solution y). At the end of this stage, the program state now contains L in the lower triangular half of the matrix A, and the solution to $Ly = b$ in the vector b. In the second stage the program solves the system $L^T x = y$ using backwards substitution (overwriting y again with the solution x), where y is the solution to the system solved in the first stage. The program subsequently returns the vector x, which is the solution to equation (1).

Part b. For testing purposes, it was necessary to create a symmetric positive definite matrix. Such a matrix was created using the *generate_positive_semidef(order, seed)* method contained in the utils file in **Listing 1**. Given an order (the dimension of the desired matrix), and an integer valued seed (used to seed the random number generator with a standard normal distribution), the function creates a random matrix, multiplies it by its transpose, and returns the result. The mathematical proof for why such a matrix is symmetric positive definite is well established. Whether or not the matrix is singular in this semidefinite method is important, and this is being checked by comparing the rank of the matrix to its order. If the rank of the matrix is not equal to the order of the matrix, then the matrix is singular and a warning is printed to the console. Note that this check still does not prevent the matrix from having a poor condition number.

Date: October 17, 2016.

Part c. The testing of the choleski implementation was conducted using the code provided under the *main()* method in **Listing 2** lines $90 - 111$. The vector x^*, corresponding to the variable x in equation (1), is randomly generated with a standard normal distribution, and subsequently multiplied by the matrix A in order to generate a third vector b (i.e $b = A \cdot x^*$). The matrix A and the vector b are subsequently supplied to the solver, and the result is compared with the vector x^* that was originally used to create b. A sample of the console output is provided in Figure 1 - the matrix A is of order 10 in this example. The error in the produced result is quantified using the 2-norm:

$$error = ||solve(A, b) - x^*||_2$$

As is seen in the console output, the error is only $2 \cdot 10^{-13}$, indeed the algorithm is producing the correct result. A possible reason for such a value of the error could be the roundoff error related to the condition of the randomly generated matrices.

FIGURE 1. Choleski Elimination Testing

Part d. A program used to solved tor the node voltages in a linear resistive network is provided in **Listing 3**. The *LinearResistiveNetworkSolver()* class is initialized with a filename from which to read the circuit description. The program, in the intializer, reads

a list of network branches (J_k, R_k, E_k) and a reduced incidence matrix from a CSV file. The format of the file is as follows: a set of rows (corresponding to each branch in the network), containing the comma separated branch current, resistance, and voltage in that respective order. Then a period is printed on a new line, to signify the end of the network data. The subsequent comma separated rows denote the incidence matrix, where each row corresponds to a node, and each column to a branch. An entry of -1 is used to indicate current entering a branch, 1 is used to indicate current leaving a branch, and 0 is used to indicate that the branch does not interact directly with the given node. The program reads the data in the file sequentially (i.e first the rows of the branch data are read, and then the rows of the incidence matrix are read). Once the data is read, the program subsequently generates a linear system of equations using the aforementioned data, and solves the system via choleski elimination.

Test Circuits. Test circuit CSV descriptions (used to test the program), and their equivalent circuit diagrams and corresponding console outputs are shown below. In each case, the console output was consistent with the analytical results obtained by hand.

QUESTION 2

Part a. To find the resistance across two diagonally opposing corners of a linear resistive N by N finite different mesh, the linear resistive network solver, provided in **Listing 3**, was used. This is the same program that was used in Question 1. The static method *create_lrn_mesh_data(N, fname)* accepts an integer, N, denoting the size of the mesh, and a filename, to which a CSV description of the created mesh should be saved. It should be noted that this method also includes in the circuit description a test source placed across the diagonal of the mesh. This test source has a voltage of $1V$, and an output resistance of 1Ω. The *main()* method in **Listing 3** - lines 166-177 - calls the appropriate methods to create the resistive finite difference mesh, and subsequently solve for all the node voltages. Once all the node voltages are known, the voltage difference between the two corners of the mesh is used to construct a simple voltage division equation that is used to solver for the equivalent resistance of the mesh.

Results. The resistances of the N by N finite difference resistive meshes are provided in Table 1.

TABLE 1. Mesh Size - Resistance

N	$Resistance(\Omega)$
2	1500.0
3	1857.14285714
4	2136.36363636
5	2365.65656566
6	2560.14434643

13	3438.81477166
14	3526.48756597
15	3608.51973873

Part b. The running time of the choleski elimination is dominated by the $O(n^3)$ flops required to carry out the choleski decomposition. Therefore, since the matrix A of equation (1) scales with dimension N^2 by N^2, the number of flops for a mesh of size N by N is $(N^2)^3$ flops or equivalently N^6 flops. This is consistent with the observations presented in Table 2, and Figure 2, which show the relationship between mesh size and running time. In addition, Figure 3 explicitly shows the $O(N^6)$ behaviour, where the plot shows the running time versus mesh size scaled down by N^6 . When the mesh size grows large, the running

time becomes less influenced by the second order effects, and the curve asymptotes to an N^6 shape. This is readily shown in the red part of the highlighted curved as the running time, when divided by N^6, gives a static proportionality constant; thereby substantiating our theoretical predictions.

TABLE 2. Mesh Size - Solution Time

N	$Time(seconds)$

14	1.115041796991136
15	1.5176349109970033

Part c. In order to take advantage of the sparse nature of the matrix A in equation (1), the lookahead modification in the choleski decomposition is not performed if the computed entry of the matrix A is equal to zero. In addition, the banded nature of the matrix is exploited by only performing computations up to a certain column index (based on the matrix bandwidth). The half bandwidth is equal to $N + 2$. In theory, the computational time taken to solve this problem should increase with N as $O(N^4)$ since the number of flops is equal to $O(b^2n)$, where b^2 is the mean square of the half bandwidth; the number of flops simplifies to $O((N + 2)^2(N^2))$, which is simply $O(N^4)$. Indeed this this is consistent with the observations presented in Table 3, and Figure 4, which show the relationship between mesh size and running time with the modified code. Figure 4 actually shows the optimized algorithm and the unoptimized algorithm plotted on top of one another. Figure 5 explicitly

FIGURE 2. Choleski Elimination Timing vs Mesh Size (No Sparsity Optimization)
shows the $O(N^2)$ behaviour, where the plot shows the running time versus mesh size scaled down by N^2. When the mesh size grows large, the running time becomes less influenced by the second order effects, and the curve asymptotes to an N^2 shape. This is readily shown in the red part of the highlighted curved as the running time, when divided by N^2, gives a static proportionality constant; thereby substantiating our theoretical predictions. It is interesting to note that the algorithm actually performs better than predictions until it asymptotes, this is likely due to the sparse optimization where look ahead modifications are not performed if the computed choleski factor is equal to zero.

Part d. The resistance versus mesh size is shown in Figure 6. It appears to be that the log natural function is a good approximation to the observations, Figure 7 shows just how well the log natural function, when shifted up to the same base point, hugs the observed measurements.

QUESTION 3

Part a. A program used to find the potentials at the nodes of a regular mesh in the air between conductors by the method of finite differences is provided in **Listing 5**. The class

FIGURE 7. Curve Fitting of Resistance vs Mesh Size
FiniteDifferencePotentialSolver() is instantiated with a floating point value, h used to denote inter-mesh spacing in a uniform fashion. The initializer creates the potentials matrix, as well as four other matrices describing the relative node spacings at every single point in the mesh. The values in these matrices scale the standard node spacing h, therefore if these spacings matrices are initialized to 1, then all the nodes will have the standard node spacing h. The *solve_sor(max_residual, omega)* method solves for the potentials at every node in the mesh using the five point difference method, and the successive over relaxation iterative method. The program terminates when the residual drops to an acceptable level, namely below the passed in *max_residual* parameter. It should also be noted that the description of the physical problem is included in **Listing 4**, this information is used by the *FiniteDifferencePotentialSolver()* class to determine the appropriate boundary conditions for specific indices in the mesh. It is also important to note that the program actually leverages all the major axes of symmetry in the given problem: one translational and two planar. That is the program only uses the resources required to solve for one corner of the cross-section of the material, applying both Dirichlet and Neumann boundary conditions appropriately. Figure 8 shows the console output solution for one corner of the structure. The matrix of values shows the potentials at different points in space relative to the conductor at the centre, and the grounded outer plan.

Part b. A plot of the number of iterations vs omega for h=0.02 is shown in Figure 9. In addition the results are tabulated in Table 4.

FIGURE 8. Console Output of Finite Difference Potential Solver (h=0.01, ω=1.5)

TABLE 4. SOR: Finite Difference Mesh with h=0.02

ω	Iterations	(0.06, 0.04)
1.0	45	40.5264910956
1.1	36	40.5264943747
1.2	27	40.526494893
1.3	17	40.5265022454
1.4	20	40.5265016154
1.5	26	40.5265040922
1.6	34	40.5265046461
1.7	47	40.5264989369
1.8	75	40.5265052427
1.9	159	40.5265027188

Part c. The values of the potential at the point (0.06, 0.04) versus 1/h are shown in Table 5 and Figure 11. The number of iterations plotted versus 1/h are also shown in Table 5 and Figure 10. It is anticipated that the potential at (0.06, 0.04) is actually equal to 38.5V based on the asymptotic behaviour of Figure 11. It is in fact interesting to note the asymptotic behaviour of the potential as we decrease the mesh spacing, and consequently increase the number of nodes. It is also interesting to note that faster-than-linear increase in the number of iterations versus 1 / h. This actually indicates that the number of iterations scales proportionally to the number of mesh points used.

Part d. The values of the potential at the point (0.06, 0.04) versus 1/h are shown in Table 6 and Figure 13 for the Jacobi method. The number of iterations plotted versus

FIGURE 9. SOR: Number of iterations vs ω (h=0.02)
TABLE 5. SOR: Finite Difference Mesh with $\omega = 1.3$

h	Iterations	(0.06, 0.04)
0.02	17	40.5265022454
0.01	18	39.2382703774
0.005	328	38.7881974828
0.0025	1171	38.6172698335

1/h are also shown in Table 6 and Figure 12. It is anticipated that the potential at (0.06, 0.04) is actually equal to $38.5V$ based on the asymptotic behaviour of Figure 13. It is in fact interesting to note the asymptotic behaviour of the potential as we decrease the mesh spacing, and consequently increase the number of nodes. It is also interesting to note that faster-than-linear increase in the number of iterations versus 1 / h. This actually indicates that the number of iterations scales proportionally to the number of mesh points used. The properties of the Jacobi plots are identical to those of the SOR method with the exception that the Jacobi method actually underperforms the SOR method in terms of the magnitude of iterations required to achieve an acceptable residual.

FIGURE 10. SOR: Number of iterations vs $1/h$ ($\omega = 1.3$)
FIGURE 11. SOR: (0.06,0.04) vs $1/h$ ($\omega = 1.3$)
Part e. The uneven node spacing is accomplished by creating a matrix of right node spacings, left node spacings, top node spacings, and bottom node spacings, which contains

TABLE 6. Jacobi Method Finite Difference Mesh with $\omega = 1.3$

h	Iterations	(0.06, 0.04)
0.02	88	40.5264917649
0.01	337	39.2382738646
0.005	1226	138.7882251067
0.0025	4365	38.6173665171

FIGURE 12. Jacobi Number of iterations vs $1/h$
information regarding the inter-node separation at each point in the mesh. When producing these spacings matrices, the program ensures that the physical width of each row and each column is still consistent with the physical dimensions of the system. These matrices are used with the modified algorithm to produce the results depicted below.

FIGURE 13. Jacobi (0.06,0.04) vs $1/h$
